Executive summary

This report implements the specified hidden 15% actuator-failure wrapper and compares DQN and Double DQN in a controlled 2 x 2 experiment. The four agents use the same seed, network, initialization procedure, optimizer, replay settings, exploration schedule, target-update cadence, duration, and fixed validation-state set. The wrapper is the only environment difference; the target calculation is the only DQN-versus-DDQN difference.

Across 250 random-policy verification episodes, 2,402 of 16,460 attempted thruster actions misfired (14.593%). The target 15% lies in the Wilson 95% interval [14.062% to 15.141%]. The internal fuel-penalty count equals the attempted-action count, and no returned info object was changed.

For the recorded single-seed study, DDQN on the modified environment achieved greedy mean reward -225.82 and safe-landing rate 3%. DQN achieved 48.02 and 44%. These values are evidence for this execution only, not a claim of statistical significance.

1. Introduction

LunarLander-v3 has an eight-dimensional continuous observation: horizontal and vertical position, horizontal and vertical velocity, angle, angular velocity, and two leg-contact indicators. Its four discrete actions are:

Action	Meaning
0	Do nothing
1	Fire left orientation engine
2	Fire main engine
3	Fire right orientation engine

Actuator failures are realistic in robotics because commands can be lost or partially ineffective through mechanical, electrical, communication, or control faults. Here, the agent selects a thruster action but may unknowingly execute no-op. This hidden replacement creates transition uncertainty: similar observed state-action pairs can lead to different physical next states.

The reward charges 0.3 for the **selected** thruster action even when it misfires. It can therefore encourage a conservative policy, but only if the learner discovers that avoiding unnecessary attempts improves long-run return. DQN can overestimate action values because a maximization over noisy estimates uses the same target network for selection and evaluation. DDQN reduces this bias by selecting the next action with the online network and evaluating that action with the target network.

2. Reproducibility and environment inspection

2.1 BITS virtual-lab installation

The environment is explicitly LunarLander-v3; no fallback version is used. On a Debian/Ubuntu-style virtual lab, install Box2D build support and this repository as follows:

```
sudo apt-get update
sudo apt-get install -y swig build-essential python3-dev
python -m pip install --upgrade pip setuptools wheel
python -m pip install -e ".[dev]"
python -c "import gymnasium as gym; env = gym.make('LunarLander-v3'); print(env.observation_space, env.action_space);
↪ env.close()"
```

If sudo is unavailable, ask the lab administrator to install swig and the compiler packages; do not silently switch LunarLander versions.

2.2 Seeding and provenance

One function seeds Python random, NumPy, PyTorch CPU, all CUDA devices, Gymnasium reset, and the action space. It also requests deterministic PyTorch algorithms and disables cuDNN benchmarking where available. Box2D, floating-point kernels, drivers, and hardware can still produce cross-platform nondeterminism, so versions and hardware are recorded.

Parameter	Shared value
Global seed	148
Training episodes per agent	800
Maximum steps per episode	1000
Evaluation episodes per agent	100
Network	8-128-128-4, ReLU
Trainable parameters	18,180
Initialization	PyTorch Linear default; same seed before every agent
Optimizer / loss	Adam / Smooth L1
Learning rate	0.0005
Discount factor	0.99
Replay capacity / batch	100,000 / 64
Learning warm-up	1,000 steps
Target update	Hard copy every 500 updates
Epsilon schedule	1.00 to 0.01 over 100,000 steps
Fixed validation states	512
Failure probability	0.15
Attempted-thruster penalty	0.3
Safe-landing bonus	50.0
Device	cpu

Recorded provenance:

- Python: 3.13.12
- Gymnasium: 1.2.3
- PyTorch: 2.13.0
- NumPy / pandas / Seaborn: 2.4.4 / 3.0.2 / 0.13.2
- Platform / logical CPUs: macOS-26.5.2-arm64-arm-64bit-Mach-O / 14
- CUDA available / device: False / None
- Device used: cpu
- Global random seed: 148
- Git commit at execution: 3eb6b9bf0e382fc67c02976cdb55ed8dde1dffa7
- Git worktree dirty at execution: True

3. Custom environment and verification - 2.5 marks

For selected action a , the wrapper samples a private RNG only when $a \in \{1, 2, 3\}$. With probability 0.15 it executes action 0; otherwise it executes a . A private RNG avoids consuming the base LunarLander RNG and hence keeps ordinary transition randomness isolated. Observation/action spaces, termination, and truncation are delegated unchanged.

The modified reward is

$$R = R_{base} - 0.3 \mathbf{1}(a \neq 0) + B,$$

where $B = 50$ only for a terminated, non-truncated transition with both legs in contact and absolute horizontal velocity, vertical velocity, and angle each strictly below 0.10. Private counters are externally readable for verification but are never inserted into the observation or returned info.

3.1 Deterministic mock-environment tests

Case	Selected	Executed	Bonus	Penalty	Info unchanged	Passed
Safe terminal	0	0	50.0	0.0	True	True
Firing + safe	2	2	50.0	0.3	True	True
Misfire + safe	2	0	50.0	0.3	True	True
Not terminated	0	0	0.0	0.0	True	True

Case	Selected	Executed	Bonus	Penalty	Info unchanged	Passed
Truncated	0	0	0.0	0.0	True	True
Left leg absent	0	0	0.0	0.0	True	True
Right leg absent	0	0	0.0	0.0	True	True
Excess x velocity	0	0	0.0	0.0	True	True
Excess y velocity	0	0	0.0	0.0	True	True
Excess angle	0	0	0.0	0.0	True	True

The automated unit suite additionally checks action 0, successful firing, misfiring, strict threshold equality, both leg contacts, truncation, unchanged spaces, invalid actions, and exact info identity.

3.2 Random-policy evidence

Measure	Recorded result
Episodes	250
Environment steps	21,912
Attempted thruster actions	16,460
Misfires	2,402
Observed misfire rate	14.593%
Absolute difference from 0.15	0.004070
Wilson 95% interval	14.062% to 15.141%
Fuel-penalty count	16,460
Fuel-penalty count equals attempts	True
Fuel-penalty mismatches	0
Returned-info identity mismatches	0
Random-policy safe bonuses observed	12

Successful-fire and forced-misfire mock cases both show the 0.3 selected-action penalty. Deterministic landing-boundary cases are authoritative for the +50 bonus because random policies do not guarantee useful landing coverage.

4. Replay, network, DQN, and DDQN - 8 marks

4.1 Replay and terminal masking

The replay buffer stores state, action, reward, next state, terminated, and truncated separately. The target masks only true terminal states:

$$y = r + \gamma(1 - \text{terminated}) Q_{\text{bootstrap}}.$$

A time-limit truncation still bootstraps because the underlying MDP state is not terminal; the episode ended due to an external horizon. This choice is explicit and unit-tested.

4.2 Shared Q-network

All experiments use the same 8-128-128-4 multilayer perceptron, ReLU activations, PyTorch Linear initialization after the same global seed, Adam, and Smooth L1 loss. It has **18,180 trainable parameters**.

4.3 The only algorithmic branch

For DQN:

$$y_{DQN} = r + \gamma(1 - t) \max_a Q_{target}(s', a).$$

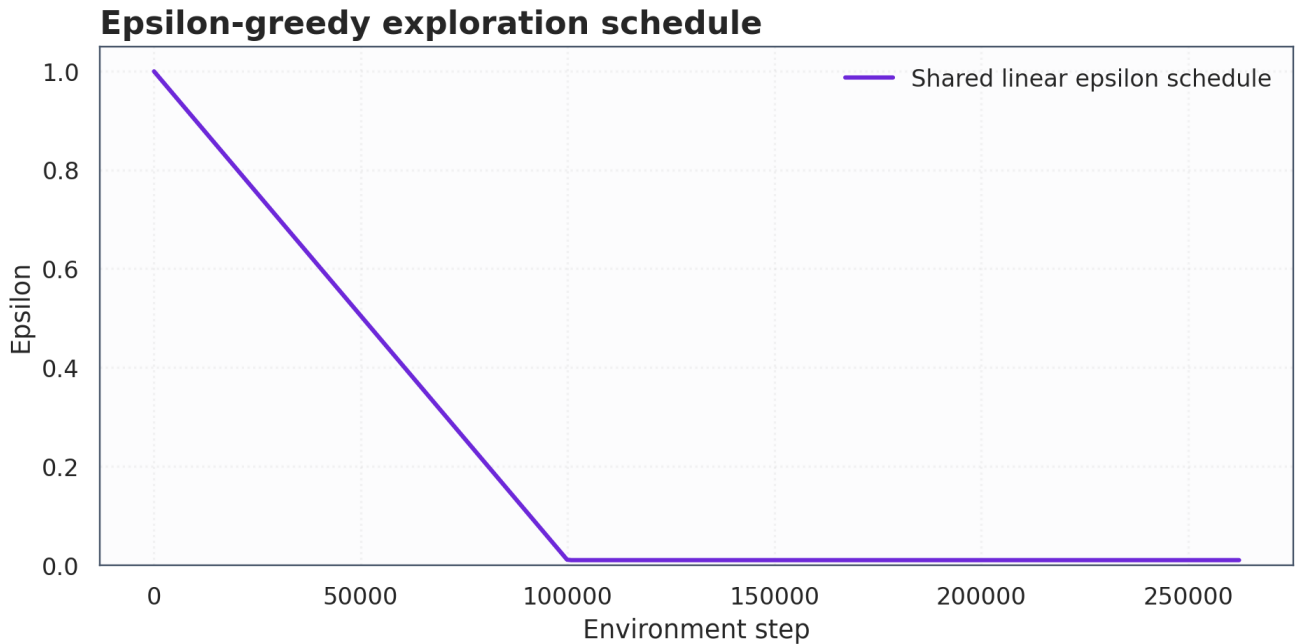

For DDQN:

$$a^* = \arg \max_a Q_{online}(s', a), \quad y_{DDQN} = r + \gamma(1 - t) Q_{target}(s', a^*).$$

The online/target architectures, optimizer, replay, epsilon policy, discount, warm-up, batch size, learning rate, target updates, seed, and training duration are otherwise identical.

4.4 Shared epsilon-greedy schedule

Checkpoint	Environment step	Epsilon
Start	0	1.000
Half decay	50000	0.505
End of decay	100000	0.010
After decay	200000	0.010

The same start, end, and step-based decay are applied to all four agents.

Figure 1: Shared epsilon-greedy schedule

5. Fixed validation states, metrics, and controlled runs

The validation states were collected once from the original environment with a reproducible random policy and never resampled during training. Reusing an identical set prevents state-distribution drift from being confused with algorithmic differences in predicted Q-values.

- Shape: (512, 8)
- SHA-256: b765a8c76d9ffa0e93207cc98d3bda2bf16adca80d38c8871380e832e25c7f8a

Every episode records reward, fixed-set average maximum Q-value, strict safe landing, moving safe-landing rate over up to 100 episodes, attempted and executed thruster actions, cumulative average attempts per episode, steps, epsilon, mean training loss, environment type, algorithm, global seed, episode seed, global step, and measured duration.

Four fresh agents and replay buffers are trained:

1. DQN - Original Environment
2. DDQN - Original Environment
3. DQN - Modified Environment
4. DDQN - Modified Environment

Each episode prints one compact progress line and writes one log record. The full study is parameterized, so a short smoke run and the full run use the same code path.

6. Performance evaluation - 2 marks

DQN vs. DDQN under stochastic actuator failure

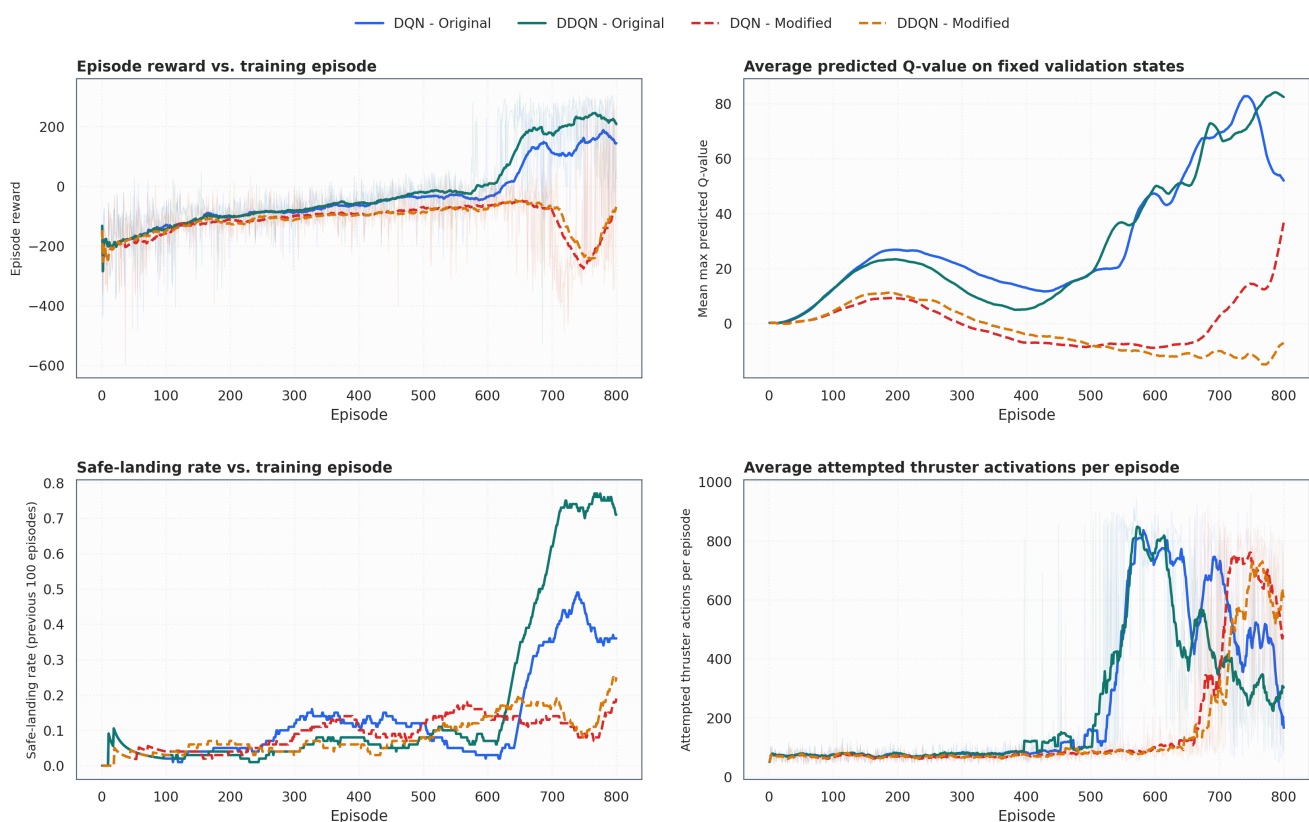

Figure 2: All four required training metrics

The figure contains the four required comparisons: episode reward, fixed-set average predicted Q-value, 100-episode moving safe-landing rate, and attempted thruster activations per episode. Raw reward and activation traces are light; moderate moving means make trends legible without concealing instability. Colours and line styles are consistent across panels.

6.1 Required final comparison table

The two panels below form one comparison table while remaining legible on A4.

Panel A - performance and value estimates

Algorithm	Environment	Mean reward final 100	Reward SD final 100	Best MA(100) reward	Final fixed-set Q	Safe rate final 100
DQN	Original	150.52	113.67	154.40	49.12	36%

Algorithm	Environment	Mean reward final 100	Reward SD final 100	Best MA(100) reward	Final fixed-set Q	Safe rate final 100
DDQN	Original	218.24	98.01	226.34	80.51	71%
DQN	Modified	-172.73	192.67	-56.87	48.56	19%
DDQN	Modified	-150.42	200.69	-54.05	-6.72	25%

Panel B - action use, successes, and duration

Algorithm	Environment	Mean attempted final 100	Mean executed final 100	Safe landings total	Training seconds
DQN	Original	409.80	409.80	116	166.63
DDQN	Original	304.11	304.11	166	137.97
DQN	Modified	655.06	557.94	86	89.09
DDQN	Modified	595.74	507.37	83	98.72

Mean reward, reward SD, safe rate, and both action-use means use the final 100 training episodes. The best moving average, final Q-value, total successes, and duration use the scopes stated in their labels. Executed actions equal attempts in the original environment; modified runs report actual non-misfired executions.

6.2 Greedy evaluation on shared seeds

Panel A - reward and strict landing performance

Algorithm	Environment	Mean reward	Reward SD	Safe landing rate
DDQN	Modified	-225.82	102.17	3%
DDQN	Original	169.05	136.75	61%
DQN	Modified	48.02	186.73	44%
DQN	Original	67.15	95.71	24%

Panel B - action use and episode length

Algorithm	Environment	Mean attempted	Mean executed	Mean steps
DDQN	Modified	730.92	622.07	972.34
DDQN	Original	250.72	250.72	360.51
DQN	Modified	423.85	359.97	615.37
DQN	Original	138.07	138.07	188.34

This evaluation uses 100 shared episode seeds per experiment and epsilon 0. It is supplementary to the assignment's final-100 training summary.

7. Discussion - 2.5 marks

7.1 Does failure increase the DQN-DDQN Q-value difference?

For this execution, yes. The final-100 mean absolute Q-gap is 16.23 in the original environment and 28.68 in the modified environment, an increase of 12.46. The fixed-state Q-value panel provides the trajectory; these numerical values provide the final-window comparison. A single seed cannot establish a population-level effect.

7.2 Why is temporal credit assignment harder?

The same selected thruster action can yield an impulse or a no-op while the agent receives no replacement indicator. Replay therefore contains higher-variance outcomes for apparently similar state-action inputs. The

attempted-action cost is charged in either case, separating a certain immediate cost from an uncertain physical effect and making delayed crash or landing credit harder to assign.

7.3 Does the 0.3 penalty encourage a conservative strategy?

Not in the attempted-action metric for this execution. Greedy DDQN attempts 730.92 actions in the modified environment versus 250.72 in the original. Greedy DQN attempts 423.85 versus 138.07. Both modified policies therefore attempt more, not fewer, thruster actions. The longer modified episodes and need to compensate for no-op commands may outweigh the 0.3 cost. The penalty alone did not produce a demonstrably conservative strategy.

7.4 Which algorithm performs better under failure?

The answer is metric-dependent. In the final 100 training episodes, DDQN has the higher mean reward (-150.42 versus -172.73) and safe-landing rate (25% versus 19%). However, frozen-checkpoint greedy evaluation strongly favors DQN: mean reward 48.02 and safe-landing rate 44% versus DDQN's -225.82 and 3%. Therefore this run does not give an unambiguous DDQN advantage and is not cleanly consistent with the theoretical expectation.

7.5 Limitation and improvement

The executed study uses one training seed, so between-run variance is not estimated. The strongest improvement is a preregistered paired multi-seed study using the same four-run design, followed by confidence intervals for final reward, safe-landing rate, Q-gap, and thruster use. A later failure-probability sweep could test whether any DDQN advantage scales with uncertainty.

8. Virtual-lab evidence

The following evidence must be genuine. Placeholders are intentional and are never substituted with fabricated screenshots.

8.0 Beginning-of-execution evidence

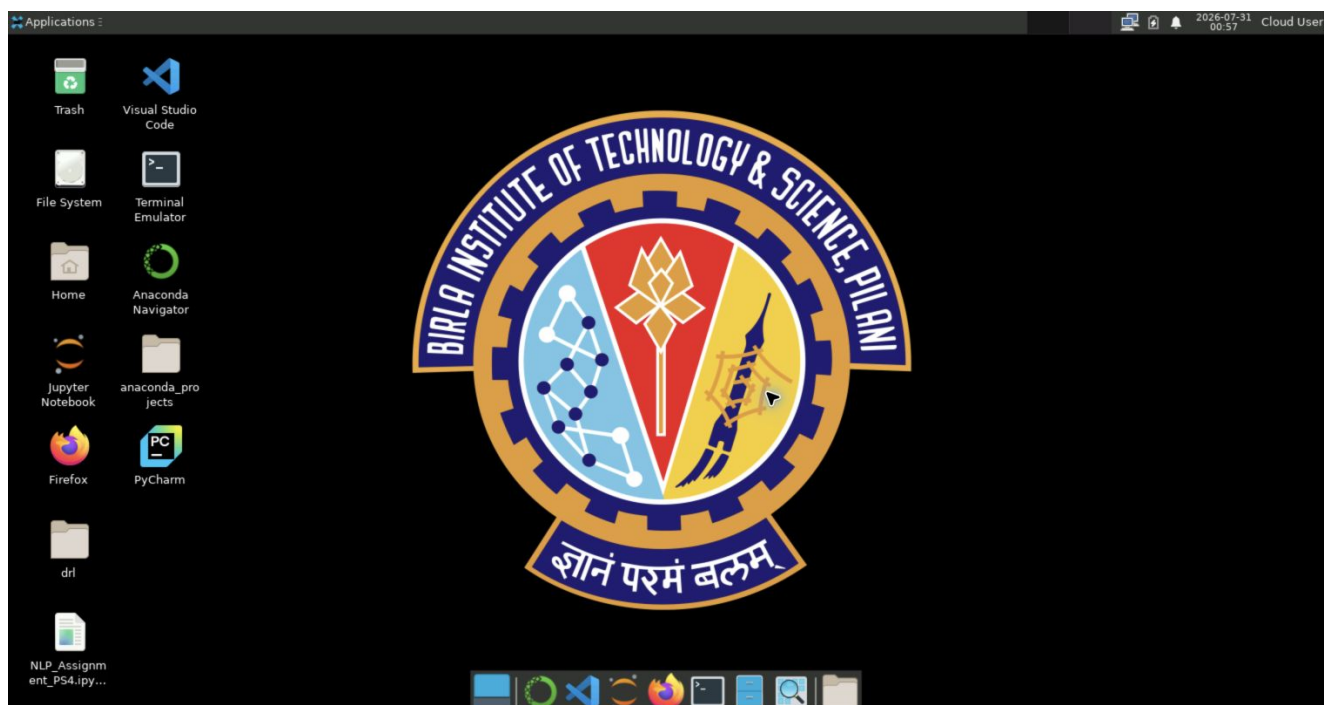

Figure 3: Beginning-of-execution timestamp and institutional virtual-lab identity

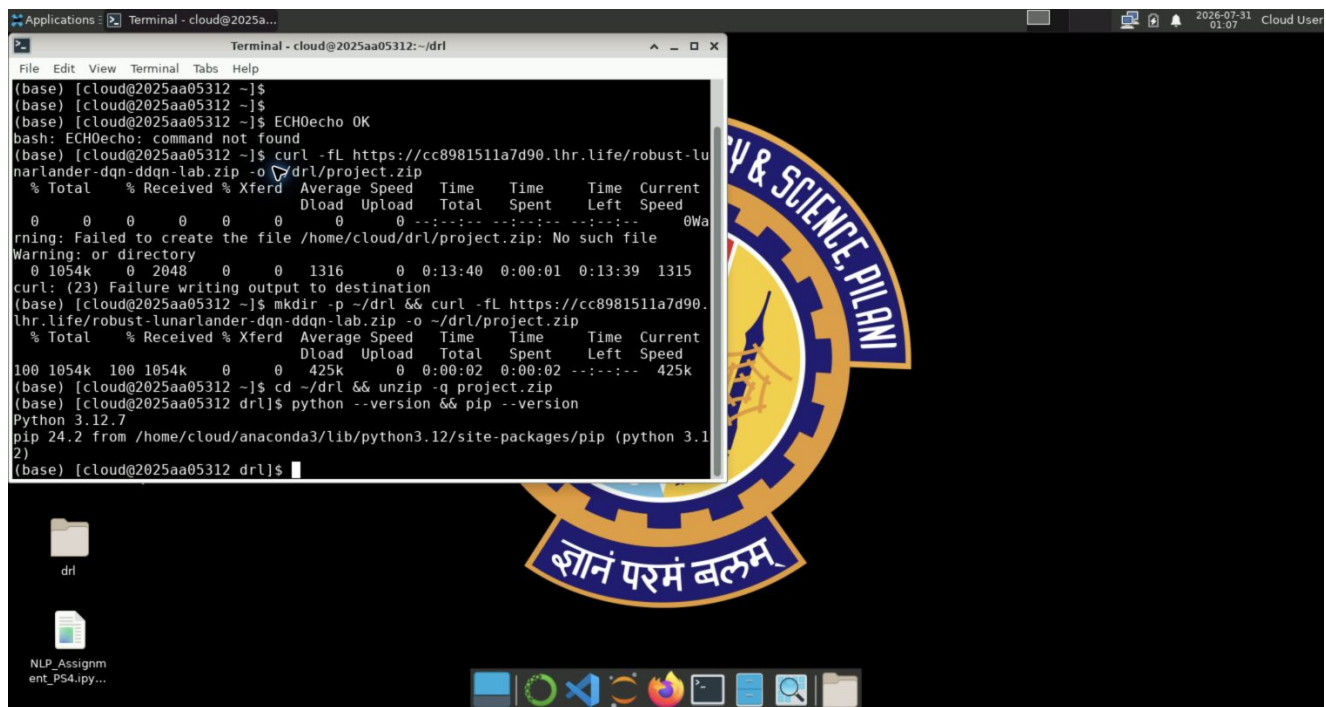

Figure 4: Environment and package-version evidence

8.1 Package and environment evidence

8.2 Timestamped training evidence

8.3 Timestamped final outputs and plots

8.4 Timestamped saved-file and checkpoint evidence

[INSERT VIRTUAL-LAB SCREENSHOT WITH VISIBLE TIMESTAMP HERE]

Timestamped saved CSV, validation-state, plot, and checkpoint evidence. Expected file:
submission/virtual_lab/05_saved_artifacts.png.

9. Conclusion

In the recorded single-seed experiment, hidden actuator failure increased the DQN-DDQN fixed-state Q-value gap from 16.23 to 28.68. The selected-action fuel penalty did not reduce attempted activations in the modified runs. DDQN was slightly stronger in the final training window, while DQN was substantially stronger in greedy evaluation, so no algorithm wins every metric. The main limitation is the single seed; paired multi-seed replication is the next improvement. This conclusion must be regenerated if the official virtual-lab run changes the recorded outputs.

Appendix B - Per-iteration output evidence

Every training episode emits a compact console line and is persisted in both a CSV ledger and a progress log. This appendix reproduces all 3,200 per-iteration records: 800 rows for each of the four controlled experiments. Values follow the compact progress output convention: reward, fixed-set average Q, moving safe-landing rate, attempted/executed thrusters, steps, epsilon, and training loss. nan denotes the pre-warm-up episodes where no gradient update was yet performed.

Experiment	CSV rows	Log records	Episode range	Complete
dqn_original	800	800	1-800	True
ddqn_original	800	800	1-800	True
dqn_modified	800	800	1-800	True
ddqn_modified	800	800	1-800	True

Table 1: Complete per-iteration training output - Dqn Original (800 episodes).

Episode	Reward	Avg. Q	Safe100	Attempted/Executed	Steps	Epsilon	Loss
1	-132.79	0.24	0.0%	51/51	71	0.9993	nan

Appendix C - Submission checklist

Use this final group checklist immediately before upload. Mark each box only after the group has verified the item in the official virtual lab and final PDF.

Final check	Confirm
Group contribution declaration is present and confirmed by all five members	[x]
All five names and BITS IDs are correct	[x]
Functions and important operations are documented	[x]
Wrapper behaviour has been experimentally verified	[x]
DQN was trained on original and modified environments	[x]
DDQN was trained on original and modified environments	[x]
The same controlled settings were used in all four experiments	[x]
All four required comparison plots are present	[x]
All five discussion questions are answered using results	[x]
Every notebook code cell was executed in the official virtual lab	[x]
Timestamped virtual-lab screenshots are included	[x]
The PDF contains code, outputs, plots, and complete per-iteration records	[x]
One group PDF is named Group148_Q_learning_DQN_DDQN.pdf	[x]
First version is submitted by 5 August 2026	[x]
Final deadline is 7 August 2026, 11:59 PM	[x]
No fabricated results or screenshots are included	[x]
Every group member has reviewed and understood the work	[x]

Rubric coverage

Rubric item	Marks Coverage
Environment implementation and verification	2.5 Sections 3.1-3.2; wrapper source; deterministic tests; random-policy CI and counter equality
DQN	4.0 Sections 4-5; shared network, replay, terminal mask, DQN target, controlled training
DDQN	4.0 Sections 4-5; online selection / target evaluation branch and controlled training
Performance evaluation	2.0 Section 6; four plots, final-100 table, and shared-seed greedy evaluation
Discussion	2.5 Section 7; all five evidence-based questions, limitation, and improvement
Total	15.0 All rubric areas mapped
